Contents

1 Overview

`cnvGSA` is an `R` package for testing the gene-set rare variant burden in case-control studies of copy number variation (CNV).

Gene-sets need to be pre-compiled based on user-curated data or publicly available gene annotations like Gene Ontology or pathways.

"Competitive" gene-set over-representation tests are commonly used to analyze differentially gene expressed genes (e.g. Fisher's Exact Test, GSEA), but they are not suitable for rare CNVs [1][2]; the most appropriate choice for rare CNVs is a "self-contained" burden test with global burden correction implemented by `cnvGSA` and other tools [2].

Global burden correction is very important. This is because for many disorders including autism and schizophrenia, the implicating rare CNV case subjects are enriched in large, recurrent CNVs that are not observed (or observed at very low frequency) in controls. In addition to this, only a minority of these genes contribute to disease risk [3][4][5][6]. In the absence of global burden correction, many gene-sets would present a biologically unspecific burden, uniquely driven by those larger and recurrent CNVs [2]. Global burden correction thus helps identifying specific pathways and functional categories implicated in disease risk by rare CNVs.

In `cnvGSA`, subjects are treated as statistical sampling units. Subject-level covariates that may act as confounders can be provided by the user (e.g. sex, ethnicity, CNV genotyping platform, CNV genotyping site, array quality metrics, etc...). The gene-set burden is tested using a logistic regression approach. Two logistic regression models are fit: model A includes the subject-level covariates and a variable quantifying global CNV burden for each subject (total CNV length, or total number of CNV-overlapped genes per subject, etc...); model B includes all variables present in model A, plus the number of CNV-overlapped genes that are members of the gene-set being tested. Presence of significantly higher burden in cases compared to controls is tested by comparing the two models using a deviance test, as implemented by `anova.glm`.

Note: only rare CNV (e.g. at frequency <1%) should be present in the input data. When analyzing the contribution of common variants to disorders with a genetic basis, a burden test is not the best approach. Earlier versions of `cnvGSA`, or highly similar burden tests, have been used in several high profile studies of rare CNV in neuropsychiatric disorders [2][4][5][6]. `cnvGSA` provides functions to visualize gene-set burden results and also to export them to the Cytoscape plugin Enrichment Map [7].

2 Workflow outline

The general procedure for performing a CNV gene-set analysis involves loading CNV, phenotype/covariate and gene-set data, setting filters and parameters, running the analysis, and reviewing the results. To facilitate these operations, the package provides `"CnvGSAInput"`, an S4 class acting as a simple container data structure with slots for each of these required inputs:

```
> library("cnvGSA")
> slotNames("CnvGSAInput")
[1] "cnvData.ls" "phData.ls" "gsData.ls" "config.ls" "params.ls"
```

The input slots should hold the following:

- `cnvData.ls` - CNV data
- `phData.ls` - Phenotype/Covariate data
- `gsData.ls` - Gene-set data
- `config.ls` - paths and file names
- `params.ls` - Test parameters

To ease the discussion here, a pre-built input object has been saved for convenience in the companion data package for this vignette:

```
> library("cnvGSAdata")
> data("cnvGSA_input_example")
> ls()

[1] "cnvGSA.in"

> class(cnvGSA.in)

[1] "CnvGSAInput"
attr(,"package")
[1] "cnvGSA"

> slotNames(cnvGSA.in)

[1] "cnvData.ls" "phData.ls" "gsData.ls" "config.ls" "params.ls"
```

Each of the slots can be accessed using an accessor function of the same name (e.g. `cnvData.ls(input)` gets or sets `cnvData.ls`, `gsData.ls(cnvGSA.in)` gets or sets `gsData.ls`, etc.).

The input object is used with `cnvGSA`'s main function, `cnvGSAlogRegTest()`:

- `cnvGSAlogRegTest( cnvGSA.in )` - Performs a gene-set association test of case vs. control subjects using logistic regression models.

This function produces an object of class `"CnvGSAOutput"` as its output – likewise a simple S4 class that has slots for each of the output elements.

```
> data("cnvGSA_output_example")
> ls()

[1] "cnvGSA.in" "cnvGSA.out"

> class(cnvGSA.out)

[1] "CnvGSAOutput"
attr(,"package")
[1] "cnvGSA"

> slotNames(cnvGSA.out)
[1] "res.ls"      "gsTables.ls" "gsData.ls"   "phData.ls"
```

The output slots contain the following:

- `res.ls` - Original and filtered CNV data
- `gsTables.ls` - Burden analysis results for gene-sets
- `gsData.ls` - Gene-set tables which look at each gene individually for each gene-set
- `phData.ls` - Phenotype/covariate data which is similar to that in `cnvGSA.in`

As with the slots in the input object, each of these can likewise be accessed using an accessor function of the same name (`gsTables.ls()` gets `gsTables.ls`, etc.).

Throughout the following sections, the pre-built `cnvGSA.in` example object from above will be shown to illustrate its typical elements. The function `cnvGSAIn` will take care of most of the processing and formatting. The most important part for the user is to make sure that the input data has all the necessary columns with the correct column names. If this is satisfied the script will take care of the rest.

3 Loading input data

The elements of a `CnvGSAInput` object – i.e. `cnvData.ls`, `phData.ls`, `gsData.ls`, `config.ls`, and `params.ls` – are easily filled when using the function `cnvGSAIn` as described above. It is more important to ensure that the input data is formatted correctly so the script will run properly. Creating the input data should look like the following pseudocode:

```
# Create input object
cnvGSA.in <- cnvGSAIn(configFile,cnvGSA.in)
```

Note that each of the elements can be observed after creating the S4 object using the accessors. The config file and each of the input files will be described below.

3.1 CNV data

The input CNV data for `cnvGSAIn` depends on feeding in the right file. The following is an example on what the CNV file should look like. The user should be sure to follow this when inputting the CNV file. All text files that are input should be tab separated. There is an example in `cnvGSAdata` that will show you what the necessary columns should be in the CNV file:

```
> cnvFile <- system.file("extdata","cnv_AGP_demo.txt",package = "cnvGSAdata")
> cnv.df <- read.table (cnvFile, header = T, sep = "\t", quote = "\"",
+ stringsAsFactors = F)
> str(cnv.df,strict.width="cut")
'data.frame': 10666 obs. of  6 variables:
 $ SID   : chr  "1020_4" "1020_4" "1020_4" "1030_3" ...
 $ CHR   : chr  "4" "6" "3" "10" ...
 $ BP1   : int  34802932 35606076 4110452 56265896 64316996 24115481 83206919..
 $ BP2   : int  35676439 35673400 4145874 56361311 64593616 24202712 83239473..
 $ TYPE  : int  3 3 1 1 1 3 1 3 3 3 ...
 $ geneID: chr  NA "2289" NA NA ...
```

- `$cnv.df` - A data frame containing the CNVs. Each row contains data for one CNV:
  - `SampleID` - ID assigned to the subject's DNA sample in which the CNV was found. The values here should match the corresponding values in the `$s2class` data frame (see below). It is assumed that the correspondence for each is always 1-to-1 with a subject.
  - `Chr` - Chromosome on which the CNV is located.
  - `BP1` - Start position of the CNV on the chromosome.
  - `BP2` - End position of the CNV on the chromosome.
  - `TYPE` - CNV type (typically `"LOSS"` or `"GAIN"`, but can be any other label indicating deletions and gains).
  - `geneID` - Genes affected by the CNV, stored in a delimited format inside a character string; e.g. `"54777;255352;84435"` for semicolon-delimited EntrezGene identifiers. (We recommend using this ID system – and in any case the example data in this vignette follows it.) CNVs that are not genic should have an empty string (i.e. `""`) in this column.

After running `cnvGSAIn` the following will be included in the `$cnvData.ls` slot

```
> str(cnvData.ls(cnvGSA.in),strict.width="cut")
List of 2
 $ cnv.df     :'data.frame': 10666 obs. of  17 variables:
  ..$ SID           : chr [1:10666] "1020_4" "1020_4" "1020_4" "1030_3" ...

  ..$ geneID_TYPE: chr [1:22322] NA NA NA NA ...
```

Its elements are as follows:

- `$cnv.df` - A data frame containing the CNVs. Each row contains data for one CNV. It has added columns to the previous description and they are:
  - `CnvKey` - Made from combining CHR, BP1, BP2, TYPE with @
  - `OlpKL_CNV` - Chromosome on which the CNV is located.
  - `OlpK_SID` - Start position of the CNV on the chromosome.
  - `SubjCnvKey` - Made from combining SID and Cnvkey using @@
  - `CnvLength_ALL` - CNV type (typically `"LOSS"` or `"GAIN"`, but can be any other label indicating deletions and gains).
  - `CnvLength_TYPE` - Genes affected by the CNV, stored in a delimited format inside a character string; e.g. `"54777;255352;84435"` for semicolon-delimited Entrez-Gene identifiers. (We recommend using this ID system – and in any case the

example data in this vignette follows it.) CNVs that are not genic should have an empty string (i.e. "") in this column.

- `CnvCount_TYPE` - Genes affected by the CNV, stored in a delimited format inside a character string; e.g. `"54777;255352;84435"` for semicolon-delimited Entrez-Gene identifiers. (We recommend using this ID system – and in any case the example data in this vignette follows it.) CNVs that are not genic should have an empty string (i.e. "") in this column.

- `$cnv2gene.df` - A data frame that is used to map the CNVs to the corresponding genes.

3.1.1 Gene ID file

One convenient thing about this package is that you can use whatever gene ID system you would like. The user just has to provide is a gene ID file that will specify which system you would like to use. This file is used to get the other meta data on the genes like the gene symbols and the gene name.

Here is an example of how to make the gene ID file with the Entrez ID system for Humans:

```
> library (org.Hs.eg.db)

> ann_eg2sy.df   <- stack (as.list (org.Hs.egSYMBOL));
> names (ann_eg2sy.df)   <- c ("Symbol", "geneID");
> ann_eg2sy.df   <- as.data.frame (lapply (ann_eg2sy.df,   as.character),
+ stringsAsFactors = F)

> ann_eg2name.df <- stack (as.list (org.Hs.egGENENAME));
> names (ann_eg2name.df) <- c ("Name",   "geneID");
> ann_eg2name.df <- as.data.frame (lapply (ann_eg2name.df, as.character),
+ stringsAsFactors = F)

> ann_eg.df <- merge (ann_eg2sy.df, ann_eg2name.df, by = "geneID", all = T)
```

3.2 Phenotype/Covariate Data

After the CNV data has been loaded the next data structure that needs to be loaded is `phData`, which contains the phenotype/covariate data. Just like the CNV data there is an example of this type of file in the package `cnvGSAdata` as well:

```
> phFile <- system.file("extdata","ph_AGP_demo.txt",package = "cnvGSAdata")
> ph.df <- read.table (phFile, header = T, sep = "\t", quote = "\"",
+ stringsAsFactors = F)
```

```
> str(ph.df)
'data.frame': 10666 obs. of  3 variables:
 $ SID      : chr  "1020_4" "1020_4" "1020_4" "1030_3" ...
 $ SEX      : chr  "Male" "Male" "Male" "Male" ...
 $ Condition: int  1 1 1 1 1 1 1 1 1 1 ...
```

The file should have these columns to be able to work with all the functions. There can be additional columns added like more covariates. This is the bare minimum format it should follow:

- `$ph.df` - A data frame containing the CNVs. Each row contains data for one CNV:
    - `SampleID` - ID assigned to the subject's DNA sample in which the CNV was found.
    - `Covariates` - The covariates that will be included in the analysis. A set of columns, which act as a character, numeric, integer or factor.
    - `Condition` - Identifies the sample as a case(1) or control(0).

After the user runs `cnvGSAIn()` there will be some additional columns and objects added to the slot:

- `$ph.df` - A data frame containing the CNVs. Each row contains data for one CNV. This column will be **added** after running `cnvGSAIn`:
    - `OlpKL_SID` - Finding those that have overlap in the CNV data frame. Maps it to the corresponding `$SID`.
- `$ph_TYPE.df` - A data frame that is a subset of `$ph.df`. This data frame only contains the events of the specified type that the user chooses in the config file (ex. "LOSS"). It will have all the same columns as `$ph.df` with the addition of every gene-set as a column. In each of these columns there will be a count of the number of desired events (ex. "LOSS") that happened for each row.

3.3 Gene sets

Before we can properly load the data, we must make sure that the data is formatted correctly. The gene-set data should be one list containing all the gene sets that the user wants to include in the analysis. This list should have names which will act as the `$GsID` for the later tables and will be the ID's for a certain gene set.

The file containing this gene-sets **must** be called `gs_all.ls` and will be a list with each entry being the gene-set named and a vector or the corresponding genes in the gene-set. There should also be a separate file that will contain the gene set names. This file **must** be named `gsid2name.chv` and will be a vector simply containing all the gene-set names. Here is an example of what they should look like:

```
> library(cnvGSAdata)
> data("gs_data_example") # gs_all.ls and gsid2name.chv will be loaded
> str(gs_all.ls,max.level=1,list.len=5)
List of 51
 $ BspanVHM_PreNat             : int [1:3038] 7105 4800 81887 6405 1595 3927 90293 ...
 $ BspanVHM_EqlNat             : int [1:3038] 8813 54467 9957 23072 8379 56603 79007 ...
 $ BspanVHM_PstNat             : int [1:3131] 2519 2729 90529 57185 22875 572 51056 ...
 $ BspanVH_lg2rpkm4.74         : int [1:4600] 7105 4800 57185 1595 572 9957 3927 ...
 $ BspanHM_lg2rpkm3.21         : int [1:4605] 8813 2519 2729 90529 81887 22875 6405 ...
  [list output truncated]
> str(gsid2name.chv)
 Named chr [1:51] "BspanVHM_PreNat" "BspanVHM_EqlNat" "BspanVHM_PstNat" ...
 - attr(*, "names")= chr [1:51] "BspanVHM_PreNat" "BspanVHM_EqlNat" ...
```

After the data is put in the correct format, the next data structure that `gsData`, which contains the gene-set data. Again, the `gsData()` function below is just an accessor function for this slot. There is an example of this in the `CnvGSAInput()` object. Too see an example, just load the `CnvGSAInput()` object from the `cnvGSAdata` package:

```
> library(cnvGSAdata)
> data("cnvGSA_input_example")
> str(cnvGSA.in@gsData.ls,strict.width="cut")
List of 7
 $ gs_info.df          :'data.frame': 52 obs. of  4 variables:

```

The list elements are:

- `$gs_info.df` - A data frame with the columns `$GsKey`, `$GsID` ,`$GsName`, `$GsSize` that is used to map the CNVs to the appropriate column
- `$gs_sel_U.df` - A data frame with the columns `$GsKey`, `$geneID`, `$GsName` that is used to map each `$GsKey` with the corresponding `$geneID`. It splits all the genes apart so that there is a one to one relationship.
- `$gs_colnames_TYPE.chv` - A single character vector that contains all the `$GsKey` elements.
- `$gs.ls` - A list containing all the gene sets and may be filtered depending on what the user specifies. The names for this list are the `$GsKey`.
- `$geneCount.tab` - A table that is used to obtain the geneCount.df data frame. It uses the `table` function in R to compare the `$geneID` with the `$Condition`.
- `$geneCount.df` - A data frame with the columns `$geneID`, `$Name`, `$Controls`, `$Cases`. This shows how many cases and controls are present for each gene.
- `$gs_all.ls` - A list containing all the gene-sets and their corresponding genes. The names for this list are the `$GsID`.

3.3.1 Including Known Loci

The option to include known loci into the analysis is available and should resemble the correct format discussed below. These files are defined in the config file. There are two files that are needed to mark the known loci. If the known loci files are properly loaded, the script will mark the known loci in `f.readData()`. The files needed are:

```
> kl_lociFile <- system.file("extdata","kl_loci_AGP_demo.txt",package = "cnvGSAdata")
> kl_loci.df <- read.table (kl_lociFile,  sep = "", header = T, comment.char = "",
```

```
+ quote = "\"", stringsAsFactors = F)
> str(kl_loci.df,strict.width="cut")
'data.frame': 56 obs. of  5 variables:
 $ CHR   : chr  "2" "2" "15" "9" ...
 $ BP1   : int  50539877 51002576 21190624 98998 50990306 50968208 28705540..
 $ BP2   : int  50730546 51157742 26203954 3682923 51222043 51214171 30436163..
 $ TYPE  : int  1 1 3 1 1 1 1 3 1 3 ...
 $ geneID: chr  "9378" "9378" "100033413;100033414;100033415;100033416;..
```

- `kl_loci.df` - Data frame that contains all the known locus for the. It should include the following columns:
  - `CHR` - Chromosome on which the CNV is located.
  - `BP1` - Start position of the CNV on the chromosome.
  - `BP2` - End position of the CNV on the chromosome.
  - `TYPE` - CNV type (typically `"LOSS"` or `"GAIN"`, but can be any other label indicating deletions and gains).
  - `geneID` - Genes affected by the CNV, stored in a delimited format inside a character string; e.g. `"54777;255352;84435"` for semicolon-delimited EntrezGene identifiers. (We recommend using this ID system – and in any case the example data in this vignette follows it.) CNVs that are not genic should have an empty string (i.e. `""`) in this column.

```
> kl_geneFile <- system.file("extdata","kl_gene_AGP_demo.txt",package = "cnvGSAdata")
> kl_gene.df <- read.table (kl_geneFile, sep = "", header = T, comment.char = "",
+ quote = "\"", stringsAsFactors = F)
> str(kl_gene.df,strict.width="cut")
'data.frame': 1 obs. of  3 variables:
 $ geneID: int 9378
 $ Symbol: chr "NRXN1"
 $ TYPE  : int 1
```

- `kl_gene.df` - Data frame that contains the genes of interest for the analysis.
  - `geneID` - Genes affected by the CNV, stored in a delimited format inside a character string; e.g. `"54777;255352;84435"` for semicolon-delimited EntrezGene identifiers. (We recommend using this ID system – and in any case the example data in this vignette follows it.) CNVs that are not genic should have an empty string (i.e. `""`) in this column..
  - `Symbol` - Gene Symbol.
  - `TYPE` - CNV type (typically `"LOSS"` or `"GAIN"`, but can be any other label indicating deletions and gains).

4 Loading test parameters from a file

To make it easier to integrate the association test into a larger bioinformatics pipeline, it is convenient to read in the parameters from an external source such as a text file. One such implementation is to record each parameter on its own line using tsv syntax:

```
param value
###############
# LogReg Config
###############
## CONFIG.LS ##
cnvFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/cnv_AGP_demo.txt"
phFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/ph_AGP_demo.txt"
geneIDFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/geneID_demo.txt"
klGeneFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/kl_gene_AGP_demo.txt"
klLociFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/kl_loci_AGP_demo.txt"
gsFile "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/gs_data_demo.RData"
outputPath "/Users/josephlugo/Documents/R/PGC2_test/Restructure_Results/8.5/testResults/
geneListFile ""
## PARAMS.LS ##

```

To update the parameters in the S4 object you simply need to change the config file and then run the function below. Once this function is run, all the changed parameters will be updated in the CnvGSAInput S4 object.

```
> cnvGSA.in <- f.readConfig(configFile,cnvGSA.in)
```

4.1 Configuring test parameters

The test requires that the user provides the necessary information to read the correct files needed for the tests to run properly. The script will go through the config file that the user will input and use these set up for different functions in the package. There are four blocks in the config file that serve different purposes. The following section will go through each block in and explain how to fill each value.

4.1.1 config.ls configuration

The `config.ls()` accessor function can be used to interact with this list. The main association test procedure accepts several files and this list will contain all the paths to the necessary input data (note that the `config.ls()` function below is just an accessor function for this slot):

```
> str( config.ls(cnvGSA.in) )
List of 9
 $ cnvFile     : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/cnv_AGP_demo.tx
 $ phFile      : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/ph_AGP_demo.txt
 $ geneIDFile  : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/geneID_demo.txt
 $ klGeneFile  : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/kl_gene_AGP_dem
 $ klLociFile  : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/kl_loci_AGP_dem
 $ gsFile      : chr "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/gs_data_demo.RD
 $ outputPath  : chr "/Users/josephlugo/Documents/R/PGC2_test/Restructure_Results/8.5/te
```

```
 $ geneListFile: chr ""
 $ config.df   :'data.frame': 37 obs. of  2 variables:
  ..$ param: chr [1:37] "cnvFile" "phFile" "geneIDFile" "klGeneFile" ...
  ..$ value: chr [1:37] "/Users/josephlugo/Documents/R/PGC2_test/cnvGSAData/cnv_AGP_demo
```

The parameters for `config.ls` are as follows:

- `cnvFile` - File name for the cnv file user would like to read in.
- `phfile` - File name for the phenotype file user would like to read in.
- `geneIDFile` - File name for the file describing the ID system used for this data.
- `klGeneFile` - File name for the file with the genes of interest.
- `klLocifile` - File name for the file with containing the loci of the genes.
- `gsFile` - File name for the gene set data the user would like to read in.
- `gsNameFile` - File name for the file that contains all the `$GsName`s for the gene sets.
- `outputPath` - Path for the folder where you would like to put your output files.
- `geneListFile` - Path for the folder containing the list of genes that the user would like to include in the regression test. This is optional and will only look a the genes in the list. Use this to look at specific genes of interest.

4.1.2 params.ls configuration

The main association test procedure accepts several parameters which specify how the user would like to run the test (note that the `params.ls()` function below is just an accessor function for this slot):

```
> str( params.ls(cnvGSA.in) )
List of 16
 $ Kl            : chr "ALL"
 $ projectName   : chr "NS"
 $ gsUSet        : chr ""
 $ cnvType       : chr "1"
 $ covariates    : chr "SEX"
 $ klOlp         : num 0.5
 $ corrections   : chr [1:4] "no_corr" "uni_gc" "tot_l" "cnvn_ml"
 $ geneSep       : chr ";"
 $ keySep        : chr "@"
 $ geneSetSizeMin: num 25
 $ geneSetSizeMax: num 1500
```

```
$ filtGs        : chr "NO"
$ covInterest   : chr "SEX"
$ thresholdSzCt : num 1
$ fLevels       : num 10
$ check_type    : chr "1"
$ cores         : num 4
```

The parameters for `params.ls` are as follows:

- `Kl` - Whether or not you would like to include known loci in the analyses. If you choose `"ALL"`, the tests will be run twice for the known loci and when there are no known loci. The default value for this is "ALL". Possible values are:
    - `"YES"` - Include known loci in analysis
    - `"NO"` - Do not include known loci in analysis
    - `"ALL"` - Produce results from both "YES" and "NO". Will create two separate data frames.
- `projectName` - This is where the user defines the type of gene-set they are using (ex. for Neurosets the user can put "NS").
- `gsUset` - This is where the user defines the gene set they would like to use as the universal gene set. *This is optional.*
- `cnvType` - The type of CNV that the user would like to use for testing. Possible values are:
    - Any value in the `$TYPE` column which may include ("1", "0", "LOSS", "GAIN", etc...). The user may have multiple levels for this column but they should only choose one for the analysis.
    - `"ALL"` - Include both the LOSSes and the GAINs in the analysis.
- `covariates` - The covariates they would like to include in the regression model. This will be a list of all the desired covariates without any spaces in between (ex. "SEX,CNV_platform"). If you choose not to include covariates you can put "NONE".
- `klOlp` - The threshold of the percentage of overlap having to do with the known loci. The default value for this is 0.5.
- `corrections` - The correction models that they would like to include in the test. Each correction model will provide different results and comparisons can be made to see the difference between all the different corrections. More than one correction can be included in the analysis. Enter as a list of corrections without any space in between. The default value for this is to use all the correction models. Possible values are:
    - `"no_corr"` - Do not include any correction in the analysis.

    - "uni_gc" - Add the universe count correction model.
    - "tot_l" - Add the total count correction model.
    - "cnvn_ml" - Add the mean length and number correction model.

- geneSep - The separator that will be used to separate the gene list in the $geneID column of the cnv.df object. Make sure that you choose the right value here. The results will be wrong is the wrong value is input. The default value for this is ";".

- keySep - The separator that will be used to separate the values in the $SubjCnvKey column of the cnv.df object. The default value for this is "@".

- geneSetSizeMax - The max number of genes that the gene sets are allowed to have. The default value for this is 25.

- geneSetSizeMin - The minimum number of genes that the gene sets are allowed to have. The default value for this is 1500.

- filtGs - Once the $geneSetSizeMax and $geneSetSizeMax parameter's have been set you can choose whether or not to include this filter in the analysis. The default value for this is "NO" Possible values are:

    - "YES" - Include the filter in the analysis.
    - "NO" - Do not include the filter in the analysis.

- covInterest - The covariate of interest that will be included in the output. There can only be one covariate chosen for this parameter.

- thresholdSzCt - The threshold for the number of events that you choose to be accepted. The default value for this is 1.

- flevels - The max amount of levels the factor $covInterest is allowed to have. The default value for this is 10.

- cores - User will set the amount of cores they want to use for the parallelization. The default value for this is the max amount of cores on the machine.

4.1.3 Visualization configuration

This package includes the ability to create visualizations from the output of the main association test. The function cnvGSAViz is described in the workflow example and it takes in these parameters:

- FDRThreshold - Will only include those that are under this number for the plots. The default value is 0.1.

- plotHeight - Vertical length of the plots. The default value is 13.

- `gsList` - text file containing list of genes that you are interested in looking at plotting. Should be comma separated with no space in between.
- `outputPathViz` - Path for the output of the visualization script.
- `labelSize` - How long you would like the labels to be on the plots. The default value is 0.7.
- `cnvGSAViz` also takes in some parameters that are defined in `params.ls`:
    - `Kl` - look at description in previous section.
    - `cnvType` - look at description in previous section.

4.1.4 Enrichment configuration

There is also a function that will create the files necessary to create an Enrichment Map. This function takes in these parameters:

- `pVal` - the p-value you would like to use for the enrichment map. The default value is "Pvalue_U_dev".
- `FDR` - the FDR value you would like to use for the enrichment map. The default value is "FDR_BH_U".
- `coeff` - the coefficient you would like to use for the enrichment map. The default value is "Coeff_U".
- `keepCoeff` - whether or not you would like to keep the negative coefficients. The default value is "YES".
- `outputPathEnr` - Path for the output of the enr script.
- `minCaseCount` - the min number of cases each gene is allowed to have. The default value is 0.
- `minControlCount` - the min number of controls each gene is allowed to have. The default value is 0.
- `minRatio` - the min case/control ratio each gene is allowed to have. The default value is 0.
- `filtGsEnr` - whether or not you would like to filter the gene-sets alowed in the GMT file. The default value is "YES".
- `f.enrFiles` also takes in some parameters that are defined in `params.ls`:
    - `Kl` - look at description in previous section.
    - `cnvType` - look at description in previous section.

Note: larger gene-sets have more statistical power; this can be taken into account by separately testing gene-sets with different sizes.

5 Full workflow example: case-control analysis of rare CNVs from the Pinto et al. 2014 ASD study

5.1 Loading the data and running the association test

The following code performs an analysis of approx. 5500 CNVs from 2000 subjects against approx. 3700 gene-sets using an `fdr_iter` of 1000. The CNV data-set consists of rare CNVs as described in Pinto et al., Nature 2014 [6], and the gene-sets are a collection imported from the Gene Ontology, KEGG, Biocarta, Reactome, and PFAM.

```
> library( "cnvGSA" )
> library( "cnvGSAdata" )

##
## Update the config file
##

## This will give you all the paths needed to update the config file
> cnvFile    <- system.file( "extdata", "cnv_AGP_demo.txt", package="cnvGSAdata" )
> phFile     <- system.file( "extdata", "ph_AGP_demo.txt", package="cnvGSAdata" )
> geneIDFile <- system.file( "extdata", "gene_ID_demo.txt", package="cnvGSAdata" )
> klGeneFile <- system.file( "extdata", "kl_gene_AGP_demo.txt", package="cnvGSAdata" )
> klLociFile <- system.file( "extdata", "kl_loci_AGP_demo.txt", package="cnvGSAdata" )
> gsFile     <- system.file( "extdata", "gs_data_demo.txt", package="cnvGSAdata" )
## make sure everything is tab separated in the config file
## look at the params above to see how to fill everything in

##
## Create the input object
##

> configFile <- (INPUT PATH TO CONFIG FILE)
> cnvGSA.in  <- CnvGSAInput() # need S4 object
> cnvGSA.in  <- cnvGSAIn(configFile)

##
## Run association test and save the output
##

> cnvGSA.out <- CnvGSAOutput() # need S4 object
> cnvGSA.out <- cnvGSAlogRegTest(cnvGSA.in, cnvGSA.out)
```

5.2 Reviewing the results

As stated in the workflow outline, the output object is a simple S4 class containing a slot for each output data structure:

```
> slotNames(cnvGSA.out)
[1] "res.ls"      "gsTables.ls" "gsData.ls"   "phData.ls"
```

Similar to the input, each of these is a list structure containing further data structures: `res.ls` contains the the results of the logistic regression tests with or without the known loci included, `gsTables.ls` contains the gene-set tables for all the gene-sets. `gsData.ls` contains all the gene-set data, and `phData.ls` contains all the pheontype/covariate data. Just as with the input object, each of these can be accessed using an accessor function of the same name.

5.2.1 res.ls results

Taking a look first at `res.ls`:

```
List of 2
 $ covAll_chipAll_TYPE_KLy.df :'data.frame': 50 obs. of  39 variables:
 $ covAll_chipAll_TYPE_KLn.df:'data.frame': 50 obs. of  39 variables:
```

The data frames `$covAll_chipAll_TYPE_KLy.df` and `$covAll_chipAll_TYPE_KLn.df` contain the actual logistic regression results. `$covAll_chipAll_TYPE_KLy.df` has the results for the tests where the known loci were included, whereas `$covAll_chipAll_TYPE_KLn.df` has the columns but the known loci are not included in these tests. The TYPE is specified by the user and will vary.

The structure of both data frames is shown in the listing below:

```
> str( cnvGSA.out@res.ls$covAll_chipAll_TYPE_KLy.df )
'data.frame': 50 obs. of  38 variables:
 $ Coeff            : num  1.461 1.03 0.41 0.821 0.392 ...

$ GsID             : chr  "FMR1_Targets_Darnell" "PSD_BayesGrant_fullset" ...
$ GsName           : chr  "FMR1_Targets_Darnell" "PSD_BayesGrant_fullset" ...
$ GsSize           : int  840 1407 4600 1230 3131 4605 927 1424 3037 116 ...
```

Each row contains results for a single gene-set. The columns are as follows:

- `GsID`, `GsName`, and `GsSize` show the gene-set's key made by the script, identifier, name, and number of member genes respectively.
- `Coeff`, `Coeff_U`, `Coeff_TL`, and `Coeff_CNML` show the gene-set's coefficients for each of the different coreection models that were used. This represents the log odds of being a case in the exposed vs. unexposed, adjusted for the covariates and whichever correction was being used.
- `Pvalue_glm`, `Pvalue_U_glm`, `Pvalue_TL_glm`, and `Pvalue_CNML_glmL` show the gene-set's p-values for each of the different correction models that were used. These p-values were obtained using the z-test.
- `Pvalue_dev`, `Pvalue_U_dev`, `Pvalue_TL_dev`, and `Pvalue_CNML_dev` show the gene-set's p-values for each of the different correction models that were used.These p-values were obtained using a deviance test.

- Pvalue_dev_s, Pvalue_U_dev_s, Pvalue_TL_dev_s, and Pvalue_CNML_dev_s show the gene-set's p-values for each of the different correction models that were used. These p-values were obtained by taking the log of the deviance p-values and multiplying it by the sign of the coefficient.
- CASE_g1n, CASE_g2n, CASE_g3n, CASE_g4n, and CASE_g5n show the percentage of samples from the cases that each gene-set has at least 1,2,3,4 and 5 events in.
- CTRL_g1n, CTRL_g2n, CTRL_g3n, CTRL_g4n, and CTRL_g5n show the percentage of samples from the controls that each gene-set has at least 1,2,3,4 and 5 events in.
- CASE_gTT and CTRL_gTT show the total number of cases and controls there are.
- CASE_Female and CASE_male show the percentage of samples from the cases that must have at least a user specified number of events and also is part of the SEX covariate. This will change depending on which covariate the user would like to see in the output.
- CTRL_Female and CTRL_male show the percentage of samples from the controls that must have at least a user specified number of events and also is part of the SEX covariate.This will change depending on which covariate the user would like to see in the output.
- FDR_BH_U, FDR_BH_TL, and FDR_BH_CNML show FDR values using three methods. FDR_BH_U is the Benjamini-Hochberg FDR for the p-values calculated using the uni_gc correction for each gene-set calculated in relation to all the gene-sets in the input. FDR_BH_TL is the same as the previous, except with the tot_l correction. FDR_BH_CNML is the same as the previous, except with the cnvn_ml correction.

5.2.2 Detailed analysis of gene-set associations

As a further aid in understanding the CNVs and genes contributing to the association results, there is gsTables.ls – a list of data frames, one for each of the gene-sets, containing information about the CNVs and corresponding genes affecting the gene-set:

```
> str( gsTables.ls, max.level=1, list.len=5 )
List of 52
 $ BspanHM_lg2rpkm3.21         :'data.frame': 707 obs. of  10 variables:
  .. [list output truncated]
 $ BspanLA_lg2rpkm.MIN         :'data.frame': 1883 obs. of  10 variables:
  .. [list output truncated]
 $ BspanML_lg2rpkm0.93         :'data.frame': 1026 obs. of  10 variables:
  .. [list output truncated]
 $ BspanVH_lg2rpkm4.74         :'data.frame': 546 obs. of  10 variables:
  .. [list output truncated]
 $ BspanVHM_EqlNat             :'data.frame': 418 obs. of  10 variables:
  .. [list output truncated]
  [list output truncated]
```

To get gsTables.ls you need to run the following:

```
> gsTables.ls <- cnvGSA.out@gsTables.ls
> gsTables.ls <- cnvGSAgsTables(cnvGSA.in,cnvGSA.out)
```

The structure of the data frame for a particular gene-set is similar to that of `cnvData$cnv` in the input:

```
> gsTables.ls[[2]][10:19,]
    geneID_TYPE                                    SubjCnvKey    SEX CHR       BP1

245 102126404   16086_1571084001    1 BspanLA_lg2rpkm.MIN BspanLA_lg2rpkm.MIN
```

(Note that the selection above shows only 10 rows from a single data frame in the list.).

Examining the data frame for a particular gene-set may reveal that its association due to certain genes may actually be better explained by *other* genes (those that have a clearer functional impact or that have previously been associated with the cases under consideration).

5.2.3 Visualizations

Once the CnvGSAOutput and CnvGSAInput S4 objects are made, you can run the `f.makeViz` to create a collection of visualizations. An example of how to run it is shown below:

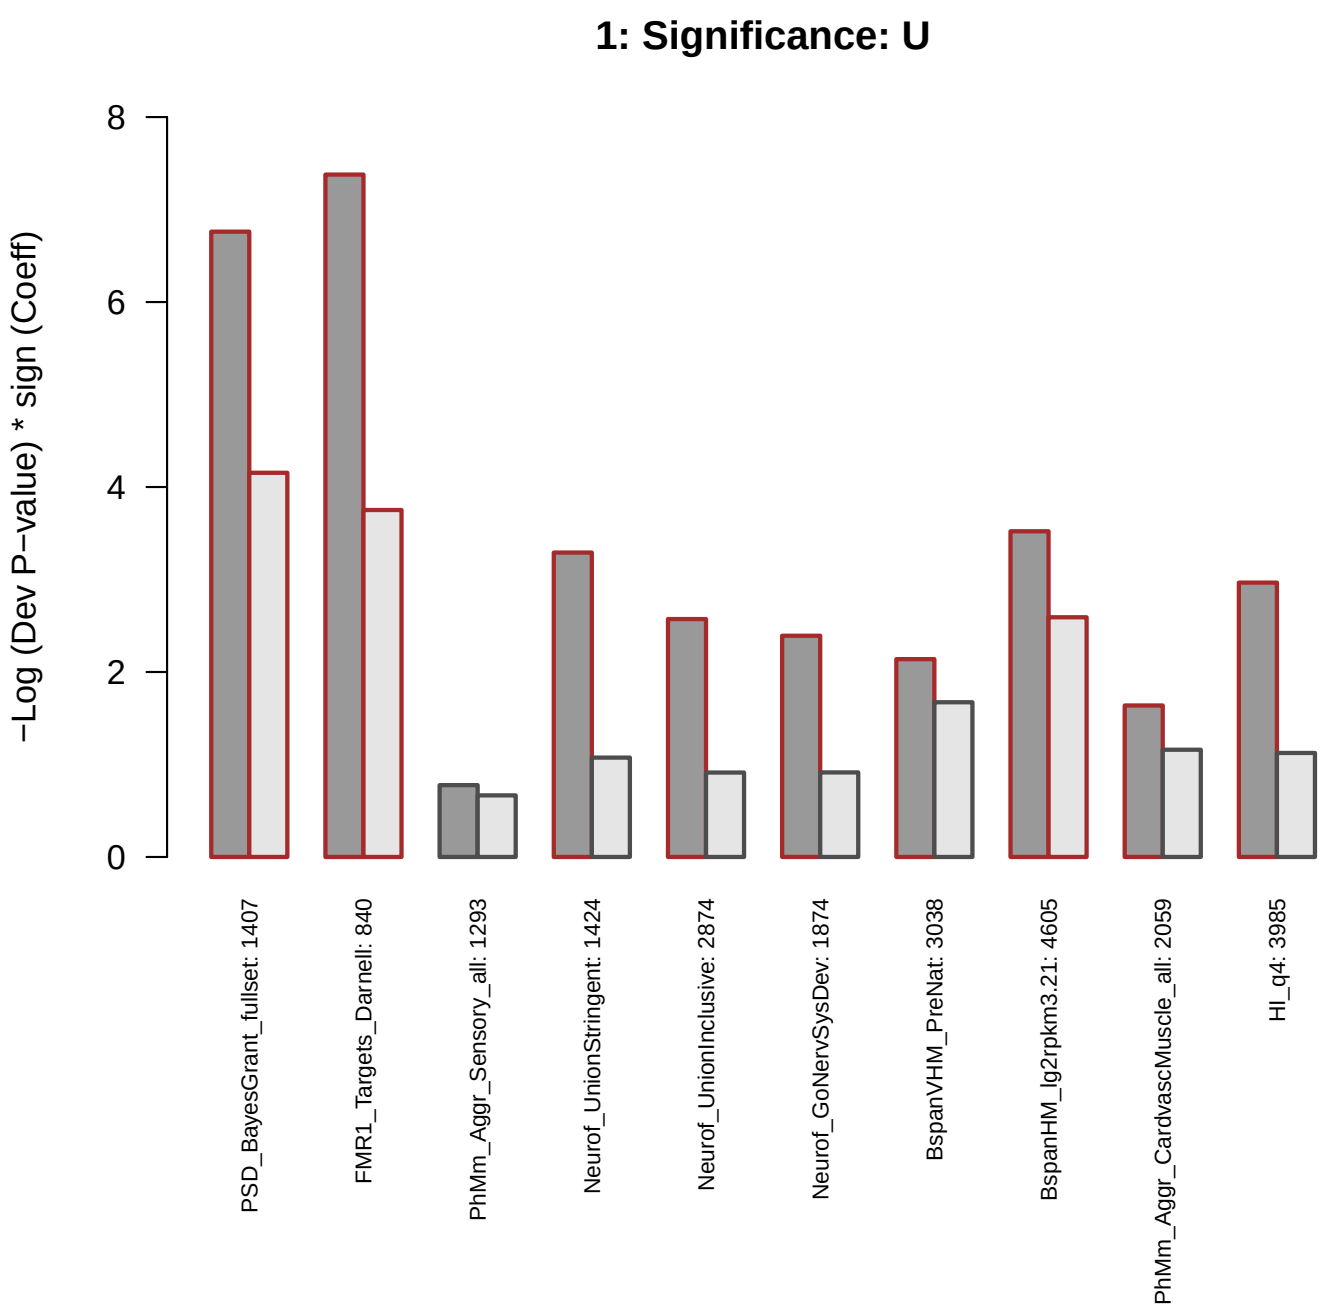
```
> library(cnvGSAdata)
> data("cnvGSA_input_example")
```

```
> data("cnvGSA_output_example")
> f.makeViz(cnvGSA.in,cnvGSA.out)
```

There are three different plots that will be made by this function. They show the significance, effect and support of the gene-sets that the user input. The significance plots will be broken down by the different corrections, so there will be a total of 3 significance plots, an effect plot, and a support plot when the function is run (5 in total). The gene-sets that will be displayed on the plot should only include ones that are particularly interesting. The user must input a comma separated file with no spaces containing all the gene-sets that they would like to look at. The file should resemble this:

```
PSD_BayesGrant_fullset,FMR1_Targets_Darnell,PhMm_Aggr_Sensory_all,
Neurof_UnionStringent,Neurof_UnionInclusive,Neurof_GoNervSysDev,BspanVHM_PreNat,
BspanHM_lg2rpkm3.21,PhMm_Aggr_CardvascMuscle_all,HI_q4
```

For the plots, anything with an FDR below the user specified cut off will have a brown border. This way the user can easily see how reliable the results are. An example of one of the plots with an FDR cut off of 0.1 is included below:



1: Significance: U
−Log (Dev P−value) * sign (Coeff)
0
2
4
6
8
PSD_BayesGrant_fullset: 1407
FMR1_Targets_Darnell: 840
PhMm_Aggr_Sensory_all: 1293
Neurof_UnionStringent: 1424
Neurof_UnionInclusive: 2874
Neurof_GoNervSysDev: 1874
BspanVHM_PreNat: 3038
BspanHM_lg2rpkm3.21: 4605
PhMm_Aggr_CardvascMuscle_all: 2059
HI_q4: 3985

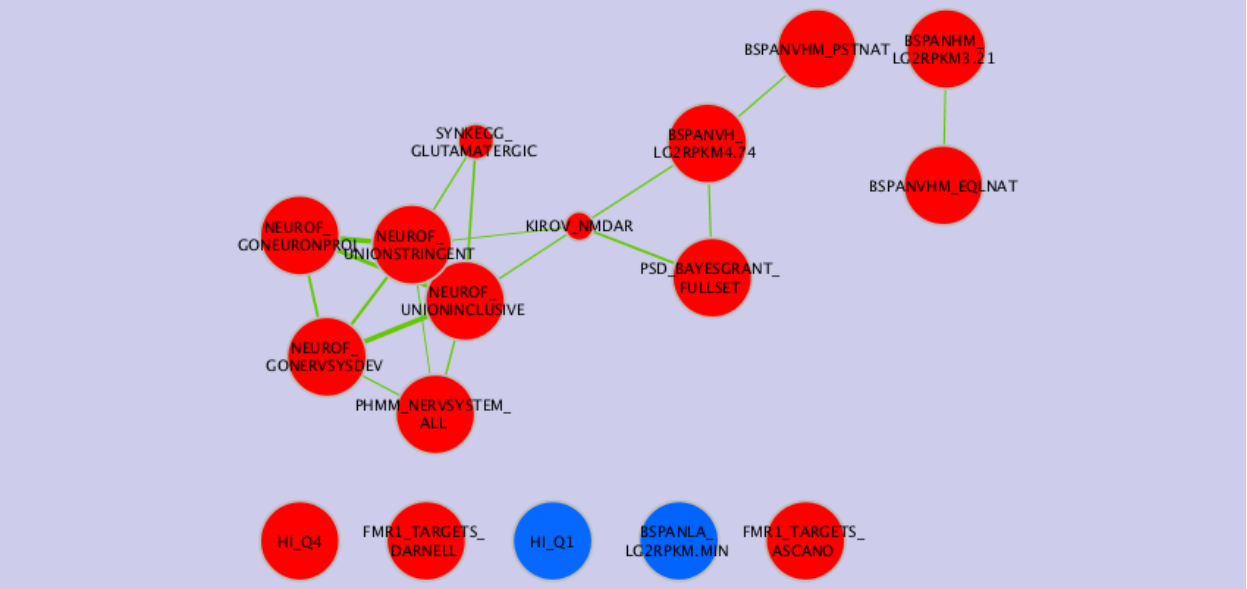
5.2.4 Enrichment Map pre-processing

To conduct further analysis of the results, this package has the function `f.enrFiles` that will do all the pre-processing for the files necessary to make an enrichment map. The enrichment map is created using Cytoscape and displays a network of gene-sets and how they interact with one another. It will produce clusters that will convey the data in a meaningful way.

The `f.enrFiles` function will create two files (GMT and generic) needed to make the enrichment map. For more information on these types of files, see the **Enrichment Map User Guide**. Once the function is run, these two files will be output and will be available to use with the **Cytoscape** software. It is recommended to use the Jaccard+Overlap combined option when creating the map. You can see a basic example below.

```
## To create the two files, simply run this function
> f.enrFiles(cnvGSA.in,cnvGSA.out)
```

The output will allow the user to use Cytoscape to create a network map that will look similar to this:



The map represents the gene-sets as nodes and links them together with edges. The closer the gene-sets are, the more similar the gene-sets are with one another. This creates clusters which make it easy to determine how the gene-sets compare to one another. The size of the node represents the size of the gene-set and the thickness of the edges is proportional to the overlap between the gene-sets. This overlap refers to the number of genes two gene-sets share with one another. In a two-class experiment such as this one, red nodes display high enrichment in one class and blue nodes display high enrichment in the second class. For a more in depth look into how to interpret these Enrichment Maps, refer to the Enrichment Map paper [7].

If you would like to use your own files to make the enrichment map they should follow the examples below. This can be found on the **Enrichment Map User Guide** as described above.

The GMT file should follow somehthing like this:

- Each row of the geneset file represents one gene-set and consists of:
    - gene-set name (–tab–) description (–tab–) a list of tab-delimited genes that are part of that gene-set.

The generic file should follow this format:

- The generic results file is a tab delimited file with enriched gene-sets and their corresponding p-values (and optionally, FDR corrections)
- The Generic Enrichment Results file needs:
    - gene-set ID (must match the gene-set ID in the GMT file),
    - gene-set name or description,
    - p-value,
    - FDR correction value
    - Phenotype: +1 or -1, to identify enrichment in up- and down-regulation, or, more in general, in either of the two phenotypes being compared in the two-class analysis (+1 maps to red and -1 maps to blue).
